

# Reviewer Guide: LLM Assisted Firewall Review

---

**Audience:** Security reviewers, architecture approvers, and BTG staff who validate firewall intent against diagrams and supporting artefacts, who may adjust organisation-wide rules, and who use the LLM Analysis experience where offered.

**Purpose:** This guide covers the **Firewall Rules Panel** for maintaining shared firewall and validation rules, the **LLM Analysis** page, tools the model may call today, and tools scheduled for later delivery.

## 1. How this fits the workflow

Project teams publish diagrams and IdaC exports. BTG links those files in the **Projects Portal** and may **Export Snapshot** so the analysis service receives structured project metadata and diagram XML. JIRA polling and batch LLM analysis populate each card **Analysis** area. The portal, **Firewall Rules Panel**, and **LLM Analysis** all call the same analysis API base URL your deployment configures for the static web UI.

The **LLM Analysis** page is a separate conversational workspace. You ask questions in natural language. The service streams answers and can invoke registered tools so responses stay grounded in stored artefacts when those tools succeed.

## 2. Firewall Rules Panel

Reviewers with permission to maintain organisation standards should use **Firewall Rules Panel** from the top navigation strip on **Projects Portal**, **LLM Analysis**, or the canvas.

### Firewall rules

Use **Add rule** to create a row. Use **Edit** on a row to open the firewall rule form. Use **Delete** to remove a rule from the working set. The browser asks you to confirm before delete.

### Validation rules

Scroll to **Validation rules**. Choose **Connection rules** or **Placement rules**. Use **Add rule** to create a validation rule. Click an existing rule row to edit it in the **Validation rule** dialog. Use the delete control on a row to remove it, with confirmation.

### Save

Choose **Save changes** in the header to store updates in this browser and refresh open diagram tabs so authors see the new effective rules.

Changes affect all diagrams that load the merged schema. Follow your change-management process for production edits.

Labelled screenshots for each action, including modal dialogs and tables before and after delete, are in the [Screenshots Walkthrough](#) Part 4.

## 3. Opening the LLM Analysis page

Use the same web application host as the canvas and portal. Choose **LLM Analysis** on the top navigation strip next to **Projects Portal** and **Firewall Rules Panel**.

The page title reads **HKMA LLM Analysis Portal**. You will see a short system introduction, a message history area, and a single input field with **Send**.

4. Prerequisites for useful answers

| Requirement                               | Why it matters                                                                                                      |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Analysis service online                   | The browser calls <code>POST /api/chat</code> on the service host your deployment configures                        |
| LLM endpoint configured on the service    | Without it the service returns guidance text instead of a live model reply                                          |
| Diagram artefacts present for the project | The primary tool reads XML that BTG pushed through <b>Export Snapshot</b> after linking a <code>.drawio</code> file |

If project teams never linked a diagram, or snapshot export did not run, the assistant can only summarise what is missing unless a demonstration diagram is available for selected codes.

5. What you can do in the LLM panel

- Ask for a structured overview of components, zones, and major flows for a project code.
- Request clarification on how diagram content relates to firewall posture at a high level.
- Step through follow-up questions once the model has loaded diagram context.
- Record the chat locally if your procedure requires audit notes. The interface does not replace your official decision log in JIRA or ARB systems.

The assistant does not automatically modify JIRA, firewall appliances, or portal records. It assists human judgement.

6. Tools available to the LLM today

The service registers a small toolkit the model may call during a turn.

| Tool                           | Status | What it does                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>getProjectDiagram</code> | Active | Loads draw.io XML for a project. Accepts <code>projectCode</code> such as CSP and optional <code>projectId</code> . It prefers diagram XML stored as analysis service artefacts from <b>Export Snapshot</b> . It may fall back to the portal snapshot copy or a packaged demonstration file when no artefact exists. Large diagrams truncate with a flag so the model knows coverage is partial. |

The model instructions direct it to cite which tool it used and to summarise diagrams at an architectural level rather than dumping raw XML.

7. Tools planned for future releases

The following tools exist in the service layer as defined stubs. They return a clear not-yet-implemented message if invoked. Your platform team will wire them to real APIs in a later iteration.

| Tool                        | Planned capability                                                                                                |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>getJiraContent</b>       | Retrieve JIRA issue fields, descriptions, and linked firewall request metadata for a given issue key.             |
| <b>getFirewallRules</b>     | Return normalised firewall rows from the IdaC workbook associated with a project after link and export workflows. |
| <b>getConfluenceContent</b> | Retrieve relevant Confluence excerpts tied to a project reference.                                                |

Until those tools return live data, treat any model statement about JIRA detail, workbook rows, or wiki text as hypothetical unless you verify manually.

## 8. Relating chat review to batch analysis

**Run Analysis** on the portal triggers the service poller and batch LLM processing tied to JIRA correlation. Results appear on each project card.

The **LLM Analysis** chat is interactive and exploratory. It can reinforce or question batch outcomes using the same underlying service host but does not replace the official **Analysis** strip for audit trails unless your process says otherwise.

## 9. Professional use practices

- State the project code explicitly in your first message when you need diagram grounding.
- Ask the model to declare which tool it relied on before you treat technical claims as verified.
- Cross-check firewall-critical conclusions against the IdaC workbook and the live JIRA request.
- Do not paste classified credentials into the chat field. Use enterprise authentication patterns your security team approves.

## 10. If something fails

| Symptom                                | What to try                                                                                            |
|----------------------------------------|--------------------------------------------------------------------------------------------------------|
| Error message about backend status     | Confirm VPN and service health. Ask operations to verify the LLM URL and key on the service host.      |
| Assistant says no diagram is available | Confirm BTG linked the <b>.drawio</b> and <b>Export Snapshot</b> completed.                            |
| Tool answers feel generic              | The model may be answering without a successful tool round trip. Rephrase with the exact project code. |
| Panel changes do not appear on canvas  | Choose <b>Save changes</b> on <b>Firewall Rules Panel</b> and refresh the diagram tab.                 |
